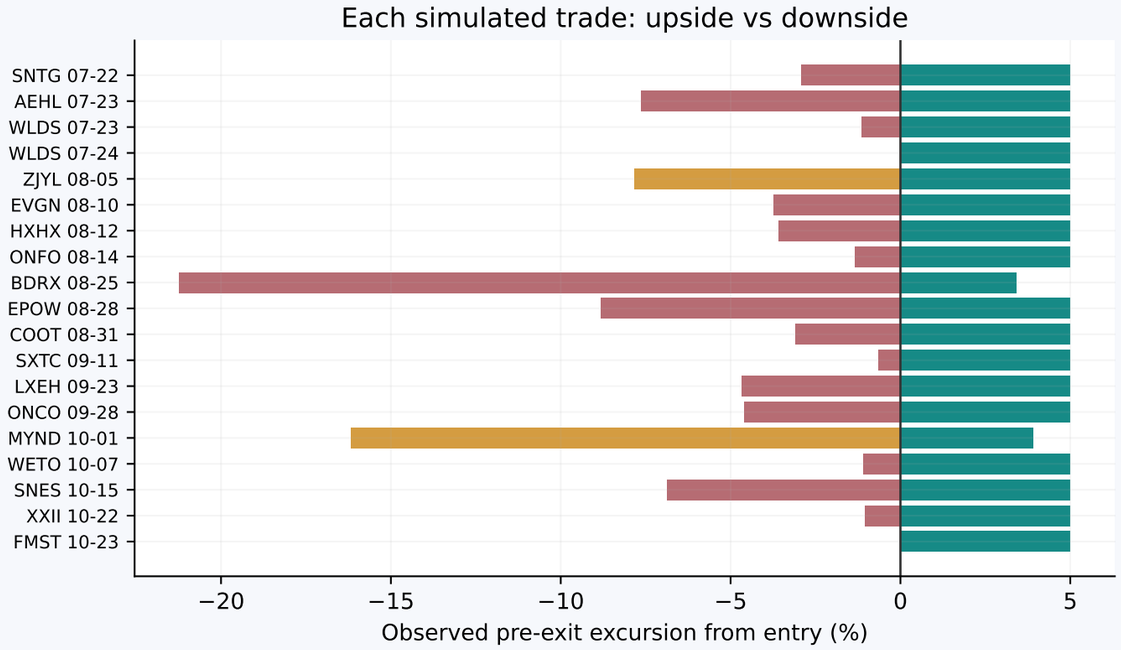
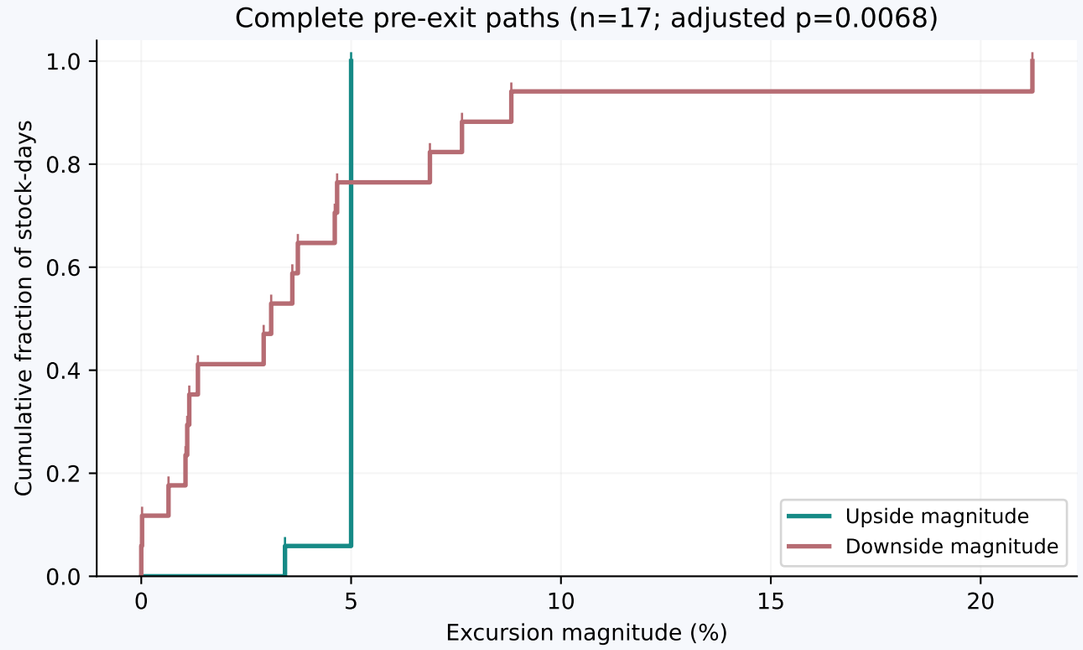
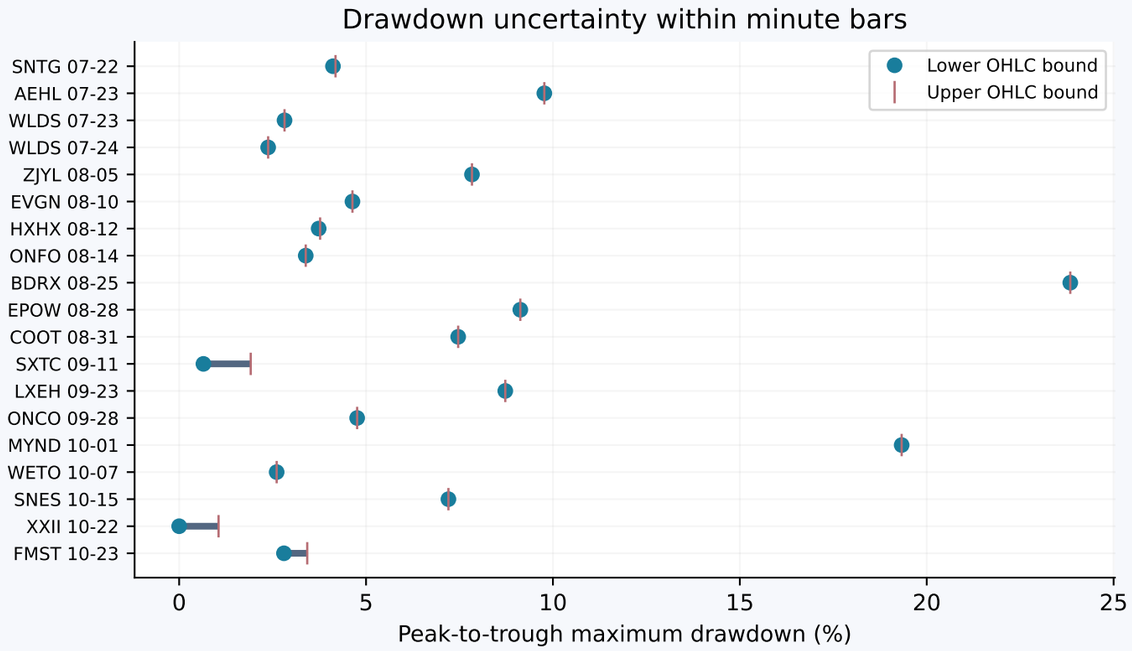
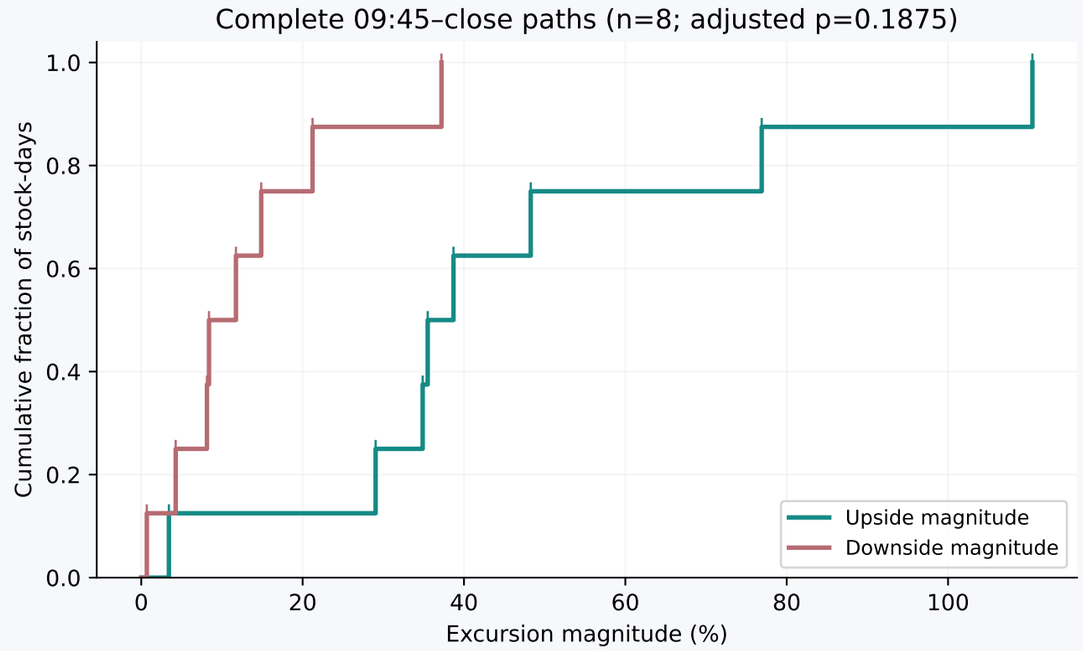
The +5% target-or-close trades — drawdowns and excursion distributions









Orange bars / flagged CSV rows have missing pre-exit minutes; their true paths are uncertain (including possible earlier target exits).

Profit-taking caps pre-exit upside at +5%, so a distribution difference is partly structural. Full-session excursions continue after the modeled exit.

Tests preserve paired observations and linked date/ticker clusters; adjusted p-values cover two planned comparisons. Small, previously viewed sample.
